بازم سؤ الات متن زير را به دقت خوانده و بر اساس متن به سؤالات داده شده با جملات انگلبسي ياسخ دهيد . DATA COMMUNICATION Data communication means transferring computerized data from one location to another. There are at least four ways in which people use data communications. One way is to send data from a CPU to peripheral devices such as printers. A second way is to communicate with remote computers over phone lines. A third way is to link office users together in local area networks. A fourth way is to link distant computers to each other in wide area networks. The term internal data transmission refers to the transfer of data within a computer, while external data transmission refers to the transfer of data to either local peripheral equipment or remote computers. In addition to transmitting data internally, a computer must transmit data to peripheral devices. It does this through computer ports that act as data gateways between the computer and its external equipment. Where peripherals are involved, it is important to distinguish between serial and parallel data transmission. Serial data transmission means the sequential transmission of bits, one following the other, through a single wire or channel. Parallel data transmission means the simultaneous transmission of bits along several wires, usually nine. Parallel data transmission 4/0 H requires that bits be assembled at starting gates like racehorses and simultaneously released down parallel wires when all bits are ready. Because nine wires are used to be transmitted at once, rather than one bit at a time, communications speeds are enhanced accordingly. This is one reason why many microcomputers use parallel data transmission for printers and other equipment. 48. What does data communication mean? (1) 49. Why do many microcomputer use parallel data transmission? (0.5) 50. Write the difference between internal data transmission and external data transmission ?(1) جمع نمرات موفق باشيد
